Chapter 1

Introduction and scenarios

1.1 Distributed Autonomous System

Each agent $i \in \{1, ..., N\}$ has

- local physical and/or cyber state x_i
- computational and sensing capabilities
- communication capability: exchange messages with "neighbours"

1.2 Scenarios and applications of distributed systems

- Averaging: distributed estimation, opinion dynamics
- Distributed control in cooperative robotics
- Distributed optimization
 - distributed machine learning
 - distributed decision-making in cooperative robotics
 - distributed optimal control in energy systems and cooperative robotics

1.3 Measurement filtering in wireless sensor networks

Consider a network of N sensors with local sensing, computation and communication. Agent $i, i \in \{1, ..., N\}$, takes a local measurement from the environment (temperature, pressure, etc.). Let $x_{i0} \in \mathbb{R}$ be the scalar local measurement Agents are interested in agreeing on the average of the measurements,

$$x_{\text{avg}} = \frac{1}{N} \sum_{i=1}^{N} x_{i0}$$

to have a better estimate of the environment quantity

Consider the following "distributed algorithm" based on "local" linear averaging, for each $i \in \{1, ..., N\}$

$$x_i^0 = x_{i0}$$

$$x_i^{k+1} = \text{average}(x_i^k, \{x_j^k, j \text{ "neighbour" of } i\}), \qquad k \in \mathbb{N}$$

generalizing coefficients of the update:

$$x_i^0 = x_{i0}$$
$$x_i^{k+1} = \sum_{j=1}^N a_{ij} x_j^k \qquad k \in \mathbb{N}$$

Remark. $a_{ij} \geq 0$ and $\sum_{j=1}^{N} a_{ij} = 1$

Remark. $a_{ij} = 0$, for some $j \in \{1, ..., N\}$, i.e. $a_{ij} = 0$ if i does not have access to the estimate of j

1.4 Parameter Estimation in Wireless Sensor Networks

Consider a network of N sensors with local sensing, computation and communication aiming at estimating a common parameter $\theta^* \in \mathbb{R}$ Each sensor i measures

$$y_i = B_i \theta^* + v_i$$

with $y_i \in \mathbb{R}^{m_1}, B_i$ known matrix and v_i a random measurement noise. Assume v_1, \ldots, v_N independent and Gaussian, with zero mean and covariance $E[v_i v_i^T] = \Sigma_i$. Assume $\sum_{i=1}^N m_i \ge m$ and $\begin{bmatrix} B_1 \\ \vdots \\ B_N \end{bmatrix}$ full rank Compute a least-squares estimate

$$\hat{\theta} = \arg\min_{\theta} \sum_{i=1}^{N} (y_i - B_i \theta)^T \Sigma_i^{-1} (y_i - B_i \theta)$$

The optimal solution is

$$\hat{\theta} = \left(\sum_{i=1}^{N} B_i^T \Sigma_i^{-1} B_i\right)^{-1} \sum_{i=1}^{N} B_i^T \Sigma_i^{-1} y_i$$

$$= \left(\frac{1}{N} \sum_{i=1}^{N} B_i^T \Sigma_i^{-1} B_i\right)^{-1} \frac{1}{N} \sum_{i=1}^{N} B_i^T \Sigma_i^{-1} y_i$$

The optimal solution can be obtained by computing two averages $\frac{1}{N}\sum_{i=1}^{N}\beta_i$ and $\frac{1}{N}\sum_{i=1}^{N}\beta_i$

1.4.1 Opinion Dynamics in Social Influence Networks

Group of N individuals, with x_i^k being the opinion of individual i at time k. Opinions are updated according to

$$x_i^{k+1} = \sum_{j=1}^{N} a_{ij} x_j^k$$

1.5 Main questions in averaging algorithms

- Do node estimates converge? Do they converge to a common value ("reach consensus")?
- Do they reach consensus to the average ("average consensus")?
- How can we model communication in general networks?
- Can we answer the above questions for general networks and communication protocols?
- What assumptions do we need on the communication network?

1.6 Distributed control in cooperative robotics

Team of N (mobile) robots aiming to execute complex tasks

Basic tasks

- rendevous, containment
- formation, flocking
- coverage

Complex tasks

- pickup and delivery
- $\bullet\,$ surveillance and patrolling
- exploration
- satellite constellation

1.6.1 Main questions in cooperative robotics

- Do robot states asymptotically converge?
- Do the asympototic staes satisfy the global, desired task?
- How can we model communication in (general) robotic networks?
- What assumptions do we need on the communication network?
- Can we answer the above questions for general networks and communication protocols?

1.6.2 Distributed optimal control

$$\begin{split} \min_{\substack{x_1,\dots,x_N\\u_1,\dots,u_N}} \sum_{i=1}^N (\sum_{\tau=0}^{T-1} \ell_i(z_{i,\tau},u_{i,\tau}) + m_i(z_{i,T})) \\ \text{subj to } \sum_{i=1}^N H_i z_{i,\tau} \leq h, & \tau \in [0,T] \\ z_{i,\tau+1} = A_i z_{i,\tau} + B_i u_{i,\tau} & \forall i,\tau \in [0,T] \\ z_{i,\tau} \in Z_i, \quad u_{i,\tau} \in U_i, & \forall i,\tau \in [0,T] \end{split}$$

Chapter 2

Preliminaries on Algebraic Graph Theory

Definition 2.0.1 (Digraph). A digraph is a pair G = (I, E) where I = 1, ..., N is a set of elements called nodes and $E \subset I \times I$ is a set of ordered node pairs called edges

Edge: the pair (i, j) denotes an edge from i to j Self-loop: edge from a node to itself, i.e. (i, i)

boy toop. edge from a floate to fiscal, flo. (t, t)

Definition 2.0.2 (Undirected (di)graph). if for any $(i, j) \in E$ then $(j, i) \in E$

Definition 2.0.3 (Subgraph). (I', E') subgraph of (I, E) if $I' \subset I$ and $E' \subset E$. Spanning subgraph if I' = I

Definition 2.0.4 (In-neighbours of i). $j \in I$ is an in-neighbour of $i \in I$ if $(j,i) \in E$

Definition 2.0.5 (Set of in-neighbours of i). $\mathcal{N}_i^{\text{IN}} = \{j \in \{1, \dots, N\} | (j, i) \in E\}$

Definition 2.0.6 (Out-neighbours of i). $j \in I$ is an out-neighbour of $i \in I$ if $(i, j) \in E$

Definition 2.0.7 (Set of out-neighbours of i). $\mathcal{N}_i^{\text{IN}} = \{j \in \{1, \dots, N\} | (i, j) \in E\}$

Definition 2.0.8 (In-degree \deg_i^{IN}). number of in-neighbours, i.e. carinality of $\mathcal{N}_i^{\text{IN}}(\deg_i^{\text{IN}} = |\mathcal{N}_i^{\text{IN}}|)$ Out-degree analogous

Definition 2.0.9 (Balanced digraph). A digraph G is balanced if $\deg_i^{\text{IN}} = \deg_i^{\text{OUT}}$ for all $i \in \{1, \dots, N\}$

Definition 2.0.10 (Complete graph). Unweighted graph such that $\forall i, j \exists (i, j), (j, i) \in E$

Chapter 3

Averaging Systems

3.1 Distributed algorithm

Given a network of N agents communicating according to a fixed digraph G, i.e. each agent i can receive messages only from in-neighbours in the graph, i.e. from $j \in \mathcal{N}_i^{\text{IN}}$. We start by considering a fixed graph, thus, each agent communicates with the same neighbours at each iteration $k \in \mathbb{N}$

$$x_i^{k+1} = \text{stf}_i(x_i^k, \{x_i^k\}_{i \in \mathcal{N}^{\text{IN}}}), \quad i \in \{1, \dots, N\}$$

where stf_i is a function depending only on state x_i and states $x_j, j \in \mathcal{N}_i^{\mathrm{IN}}$.

Alternative version with out-neighbours:

$$x_i^{k+1} = \operatorname{stf}_i(\{x_j\}_{j \in \mathcal{N}_i^{\text{OUT}}})$$

3.2 Discrete-time averaging systems

Let $G^{\text{comm}} = (I, E)$ be a fixed (communication) digraph (self loops included). A linear averaging distributed algorithm can be written as:

$$x_i^{k+1} = \sum_{J \in \mathcal{N}_i^{\text{IN}}} a_{ij} x_j^k \qquad i \in \{1 \dots, N\}$$

where $x_i^k \in \mathbb{R}$ is the state of agent i at k and $a_{ij} > 0$ are positive weights.

Remark. The weights a_{ij} are defined only for $(i,j) \in E$

Wach i uses only the states of neighbours $j \in \mathcal{N}_i^{\text{IN}}$, thus distributed algorithm.

For analysis purposes, let us define weights $a_{ij} = 0$ for $(j,i) \notin E$. Thus we can rewrite the distributed algorithm as

$$x_i^{k+1} = \sum_{i=1}^{N} a_{ij} x_j^k \qquad i \in \{1, \dots, N\}$$

This is a LTI autonomous system

$$\begin{bmatrix} x_1^{k+1} \\ \vdots \\ x_N^{k+1} \end{bmatrix} = \begin{bmatrix} a_{11} & \cdots & a_{1N} \\ \vdots & \ddots & \vdots \\ a_{N1} & \cdots & a_{NN} \end{bmatrix} \begin{bmatrix} x_1^k \\ \vdots \\ x_N^k \end{bmatrix}$$

Which can be compactly written as

$$x^{k+1}0Ax^k$$

Remark. The matrix A can be seen as the weighted adjacency matrix of the reverse digraph $G^{\text{comm,rev}}$ of the digraph G^{comm}

If instead of in-neighbours we use out-neighbours, we call the digraph a sensing digraph G^{sens} . In this case the notation becomes consistent with graph theory, so we get

$$x^{k+1} = Ax^k$$

where A can be seen as the weighted adjacency matrix of the sensing digraph G^{sens}

3.3 Stochastic matrices

The non-negative square matrix $A \in \mathbb{R}^{N \times N}$ is

- row stochastic if A1 = 1 (each row sums to 1)
- column stochastic if $A^{\top} \mathbf{1} = \mathbf{1}$ (each column sums to 1)
- doubly stochastic if both row and column stochastic.

Lemma. Let A be a row-stochastic matrix and G the associate digraph. If G is strongly connected and aperiodic, then

- 1. the eigenvalue $\lambda = 1$ is simple;
- 2. all the other eigenvalues μ satisfy $|\mu| < 1$

Remark. The condition "G contains a globally reachable node and the subgraph of globally reachable noes is aperiodic" is necessary and sufficient

Theorem 3.3.1 (Consensus). Consider a (discrete-time) averaging system with associated digraph G and wieghted adjacency matrix A. Assume G is strongly connected and aperiodic, and A is row stochastic. Then

1. there exists a left eigenvector $w \in \mathbb{R}^N$, w > 0 (i.e. with positive components $w_i > 0$ for all i = 1, ..., N) such that

$$\lim_{k \to \infty} x^k = \mathbf{1} \frac{w^\top x^0}{w^\top \mathbf{1}} = \begin{bmatrix} 1 \\ \vdots \\ 1 \end{bmatrix} \frac{\sum_{i=1}^N w_i x_i^0}{\sum_{i=1}^N w_i}$$

i.e., consensus is reached to $\frac{\sum_{i=1}^{N}w_{i}x_{i}^{0}}{\sum_{i=1}^{N}w_{i}}$

2. if additionally A is doubly stochastic, then

$$\lim_{k \to \infty} x^k = \begin{bmatrix} 1 \\ \vdots \\ 1 \end{bmatrix} \frac{\sum_{i=1}^N x_i^0}{N}$$

i.e., average consensus is reached

3.4 Example: Metropolis-Hastings weights

Given an undirected unweighted graph G with edge set E and degrees d_1, \ldots, d_n

$$a_{ij} = \begin{cases} \frac{1}{1 + \max\{d_i, d_j\}} & \text{if } (i, j) \in E \text{ and } i \neq j \\ 1 - \sum_{h \in \mathcal{N}_i \setminus \{i\}} a_{ih} & \text{if } i = j \\ 0 & \text{otherwise} \end{cases}$$

Result: the matrix A is symmetric and doubly-stochastic.
